- Calculus of variation
- Optimal Control

Piecewise-smooth extremals

- So far we focused on admissible $x(t)$ that are continuous with continuous first derivatives
- We want to expand to class if piecewise-smooth admissible functions
 - control input is no smooth (e.f., subject to saturation)

Illustration of a piecewise continuous control $u \in \hat{C}[t_0, t_f]$ (red line), and the corresponding piecewise continuously differentiable response $x \in \hat{C}^1[t_0, t_f]$ (blue line).

- intermediate state constraints are imposed

Objective: determine vector function $x^*(t)$ in the class of functions with *piecewise-continuous* first derivative that is a local extremum of

$$J(x(t)) = \int_{t_0}^{t_f} g(x(t), \dot{x}, t) dt$$

and respects $x(t_0) = x_0 \in \mathbb{R}^n$, $x(t_f) = x_f$ for given and fixed t_0 , x_0 , t_f and x_f

Piecewise-smooth extremal

Objective: determine vector function $x^*(t)$ in the class of functions with *piecewise-continuous* first derivative that is a local extremum of

$$J(x(t)) = \int_{t_0}^{t_f} g(x(t), \dot{x}, t) dt$$

and respects $x(t_0) = x_0 \in \mathbb{R}^n$ for given and fixed t_0 , x_0 , t_f and $x(t_f)$

- Assume \dot{x} has a discontinuity at $t_1 \in (t_0, t_f)$, where t_1 is not fixed (or known)

$$J(x(t)) = \int_{t_0}^{t_f} g(x(t), \dot{x}, t) dt = \underbrace{\int_{t_0}^{t_1} g(x(t), \dot{x}, t) dt}_{J_1} + \underbrace{\int_{t_1}^{t_f} g(x(t), \dot{x}, t) dt}_{J_2} \text{ as before}$$

$$\delta J = \delta J_1 + \delta J_2 =$$

$$\int_{t_0}^{t_1} \left(\frac{\partial g}{\partial x} \delta x + \frac{\partial g}{\partial \dot{x}} \delta \dot{x} \right) dt + g(t_1^-) \delta t_1 +$$

$$\int_{t_1}^{t_f} \left(\frac{\partial g}{\partial x} \delta x + \frac{\partial g}{\partial \dot{x}} \delta \dot{x} \right) dt - g(t_1^+) \delta t_1$$

Piecewise-smooth extremal

$$\delta J = \int_{t_0}^{t_1} (g_x - \frac{d}{dt} g_{\dot{x}}) \delta x dt + g(t_1^-) \delta t_1 + g_{\dot{x}}(t_1^-) \delta x(t_1^-)$$

$$\int_{t_1}^{t_f} (g_x - \frac{d}{dt} g_{\dot{x}}) \delta x dt - g(t_1^+) \delta t_1 - g_{\dot{x}}(t_1^+) \delta x(t_1^+)$$

from lefthand side $\delta x_1 = \delta x(t_1^-) + \dot{x}(t_1^-) \delta t_1$,

from righthand side $\delta x_1 = \delta x(t_1^+) + \dot{x}(t_1^+) \delta t_1$,

- Continuity requires that these two expressions for δx_1 be equal
- Already now that it is possible $\dot{x}(t_1^-) \neq \dot{x}(t_1^+)$, so possible that $\delta x(t_1^-) \neq \delta x(t_1^+)$

$$\delta J = \int_{t_0}^{t_1} (g_x - \frac{d}{dt} g_{\dot{x}}) \delta x dt + [g(t_1^-) - g_{\dot{x}}(t_1^-) \dot{x}(t_1^-)] \delta t_1 + g_{\dot{x}}(t_1^-) \delta x_1$$

$$\int_{t_1}^{t_f} (g_x - \frac{d}{dt} g_{\dot{x}}) \delta x dt - [g(t_1^+) - g_{\dot{x}}(t_1^+) \dot{x}(t_1^+)] \delta t_1 - g_{\dot{x}}(t_1^+) \delta x_1$$

$$\frac{\partial g}{\partial x}(x^*(t), \dot{x}^*(t), t) - \frac{d}{dt} \left[\frac{\partial g}{\partial \dot{x}}(x^*(t), \dot{x}^*(t), t) \right] = 0, \quad t \in (t_0, t_f)$$

$$x^*(t_0) = x_0,$$

Weierstrass-Erdmann Condition $\left\{ \begin{array}{l} g_{\dot{x}}(t_1^-) = g_{\dot{x}}(t_1^+), \\ g(t_1^-) - g_{\dot{x}}(t_1^-) \dot{x}(t_1^-) = g(t_1^+) - g_{\dot{x}}(t_1^+) \dot{x}(t_1^+) \end{array} \right.$

Piecewise-smooth extremal

Typical scenarios that introduce corners is when there exists intermediate constraints

$$x(t_1) = \theta(t_1)$$

- Constraint couples the allowable variations in δx_1 and δt_1

$$\delta x_1 = \frac{d\theta}{dt} \delta t_1 = \dot{\theta}(t_1) \delta t_1$$

- $\delta J = \int_{t_0}^{t_1} (g_x - \frac{d}{dt} g_{\dot{x}}) \delta x dt + [g(t_1^-) - g_{\dot{x}}(t_1^-) \dot{x}(t_1^-)] \delta t_1 + g_{\dot{x}}(t_1^-) \delta x_1 + \int_{t_1}^{t_f} (g_x - \frac{d}{dt} g_{\dot{x}}) \delta x dt - [g(t_1^+) - g_{\dot{x}}(t_1^+) \dot{x}(t_1^+)] \delta t_1 - g_{\dot{x}}(t_1^+) \delta x_1$
 $\delta J = \int_{t_0}^{t_1} (g_x - \frac{d}{dt} g_{\dot{x}}) \delta x dt + [g(t_1^-) - g_{\dot{x}}(t_1^-) \dot{x}(t_1^-)] \delta t_1 + g_{\dot{x}}(t_1^-) (\dot{\theta}(t_1^-) \delta t_1) + \int_{t_1}^{t_f} (g_x - \frac{d}{dt} g_{\dot{x}}) \delta x dt - [g(t_1^+) - g_{\dot{x}}(t_1^+) \dot{x}(t_1^+)] \delta t_1 - g_{\dot{x}}(t_1^+) (\dot{\theta}(t_1^+) \delta t_1)$

$$\frac{\partial g}{\partial x}(x^*(t), \dot{x}^*(t), t) - \frac{d}{dt} \left[\frac{\partial g}{\partial \dot{x}}(x^*(t), \dot{x}^*(t), t) \right] = 0, \quad t \in (t_0, t_f)$$

$$x^*(t_0) = x_0,$$

$$g(t_1^-) + g_{\dot{x}}(t_1^-) [\dot{\theta}(t_1^-) - \dot{x}(t_1^-)] = g(t_1^+) + g_{\dot{x}}(t_1^+) [\dot{\theta}(t_1^+) - \dot{x}(t_1^+)]$$

$$x(t_1) = \theta(t_1)$$

- Note here that $g_{\dot{x}}(t_1^-) = g_{\dot{x}}(t_1^+)$ no longer is needed. Instead we have $x(t_1) = \theta(t_1)$.

Piecewise-smooth extremal: Example

Example: Find the shortest length path joining the points $x = 0$, $t = -2$ and $x = 0$ and $t = 1$ that touches the curve $x = t^2 + 3$ at some point.

Solution is the dashed blue lines

Optimal control

We are going to focus on solving

$$\mathbf{u}^*(t) \Big|_{t \in [t_0, t_f]} = \underset{\mathbf{u}(t) \in \mathcal{U}}{\operatorname{argmin}} (J = h(\mathbf{x}(t_f), t_f) + \int_{t_0}^{t_f} g(\mathbf{x}(t), \mathbf{u}(t), t)) dt, \text{ s.t.}$$

$$\dot{\mathbf{x}}(t) = \mathbf{a}(\mathbf{x}(t), \mathbf{u}(t), t),$$

$$\mathbf{x}(t_0), t_0 \text{ is given,}$$

$$\mathbf{m}(\mathbf{x}(t_f), t_f) = 0 \leftarrow \text{when final state is constrained,}$$

$$\mathbf{x}(t) : \mathbb{R} \rightarrow \mathbb{R}^n, \quad \mathbf{u}(t) : \mathbb{R} \rightarrow \mathbb{R}^m, \quad f : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R} \rightarrow \mathbb{R}^n.$$

- Use Lagrange multiplier to write

$$J = h(\mathbf{x}(t_f), t_f) + \int_{t_0}^{t_f} (g(\mathbf{x}(t), \mathbf{u}(t), t) + \mathbf{p}(t)^\top (\mathbf{a}(\mathbf{x}(t), \mathbf{u}(t), t) - \dot{\mathbf{x}}(t))) dt$$

Optimal control

We are going to focus on solving

$$\mathbf{u}^*(t) \Big|_{t \in [t_0, t_f]} = \underset{\mathbf{u}(t) \in \mathcal{U}}{\operatorname{argmin}} (J = h(\mathbf{x}(t_f), t_f) + \int_{t_0}^{t_f} g(\mathbf{x}(t), \mathbf{u}(t), t) dt, \text{ s.t.}$$

$$\dot{\mathbf{x}}(t) = \mathbf{a}(\mathbf{x}(t), \mathbf{u}(t), t),$$

$$\mathbf{x}(t_0), t_0 \text{ is given,}$$

$$\mathbf{m}(\mathbf{x}(t_f), t_f) = 0 \leftarrow \text{when final state is constrained,}$$

$$\mathbf{x}(t) : \mathbb{R} \rightarrow \mathbb{R}^n, \quad \mathbf{u}(t) : \mathbb{R} \rightarrow \mathbb{R}^m, \quad f : \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R} \rightarrow \mathbb{R}^n.$$

- Use Lagrange multiplier to write

$$J = h(\mathbf{x}(t_f), t_f) + \int_{t_0}^{t_f} (g(\mathbf{x}(t), \mathbf{u}(t), t) + \mathbf{p}(t)^\top (\mathbf{a}(\mathbf{x}(t), \mathbf{u}(t), t) - \dot{\mathbf{x}}(t))) dt$$

- Define the **Hamiltonian** to help with sorting out the equations

$$H(\mathbf{x}, \mathbf{u}, \mathbf{p}, t) = g(\mathbf{x}(t), \mathbf{u}(t), t) + \mathbf{p}(t)^\top \mathbf{a}(\mathbf{x}(t), \mathbf{u}(t), t)$$

$$\delta J_a = (\mathbf{h}_x - \mathbf{p}(t_f))^T \delta \mathbf{x}_f + \left[\mathbf{h}_{t_f} + \mathbf{g} + \mathbf{p}^T (\mathbf{a} - \dot{\mathbf{x}}) + \mathbf{p}^T \dot{\mathbf{x}} \right]_{t_f} \delta t_f + \int_{t_0}^{t_f} \left[(\mathbf{H}_x + \dot{\mathbf{p}})^T \delta \mathbf{x}(t) + \mathbf{H}_u^T \delta \mathbf{u}(t) + (\mathbf{a} - \dot{\mathbf{x}})^T \delta \mathbf{p}(t) \right] dt$$

first order conditions for extremal solution

$$\begin{aligned} \dot{\mathbf{p}} &= -\mathbf{H}_x, && \text{(n dimensional)} \\ 0 &= \mathbf{H}_u, && \text{(m dimensional)} \\ 0 &= \mathbf{H}_p \rightarrow \dot{\mathbf{x}} = \mathbf{a}(\mathbf{x}, \mathbf{u}, t), && \text{(n dimensional)} \end{aligned}$$

Boundary conditions $\mathbf{x}(t_0) = \mathbf{x}_0$, and

- if t_f free

$$\mathbf{h}_{t_f} + \mathbf{g} + \mathbf{p}^T \mathbf{a} = \mathbf{h}_{t_f} + \mathbf{H}(t_f) = 0$$

- if $x_i(t_f)$ is fixed: $x_i(t_f) = x_{i_f}$
- if $x_i(t_f)$ is free, then $p_i(t_f) = \frac{\partial h}{\partial x_i}(t_f)$

Constrained functional optimization: example

- Minimum-time path through a region of position dependent vector velocity (Zernelo's problem)

Example of an ocean current vector field

- The forward velocity of the ship V is constant but its steering angle θ can be controlled.
- in the depicted example, it is assume that the current's velocity vector is only in x direction

see [Bryson and Ho]

Next couple of slides are for self-study

Constrained functional optimization

Determine vector function $w^*(t) : \mathbb{R} \rightarrow \mathbb{R}^{n+m}$ in the class of functions with continuous first derivative that is a local extremum of

$$J(w(t), t) = \int_{t_0}^{t_f} g(w(t), \dot{w}, t) dt$$

and respects

$f(w(t), \dot{w}(t), t) = 0_n$, set of n differential equations,

$w(t_0) = w_0 \in \mathbb{R}^{n+m}$,

$w(t_f) = w_f$ various terminal conditions possible.

- in control problems $w = \begin{bmatrix} u \in \mathbb{R}^m \\ x \in \mathbb{R}^n \end{bmatrix}$

To derive the first order necessary conditions we proceed with the following

- Similar to function parameter optimization, augment the cost functional with the constraint using Lagrange multiplier

$$J_a(w(t), t) = \int_{t_0}^{t_f} \left(g(w(t), \dot{w}, t) + p(t)^T f(w(t), \dot{w}, t) \right) dt$$

- Notice that $p(t)$ is time-varying (gives more degree of freedom)
- If constraint is satisfied the augmented cost functional is same as $J(w(t), t)$

Constrained functional optimization (cont'd)

- Let

$$g_a(\mathbf{w}(t), \mathbf{p}(t), \dot{\mathbf{w}}(t), t) \equiv g(\mathbf{w}(t), \dot{\mathbf{w}}(t), t) + \mathbf{p}(t)^\top \mathbf{f}(\mathbf{w}(t), \dot{\mathbf{w}}(t), t)$$

- Then

$$J_a(\mathbf{w}(t), \mathbf{p}(t), \delta \mathbf{x}, \delta \mathbf{p}, t) = \int_{t_0}^{t_f} \left(g_a(\mathbf{w}(t), \mathbf{p}(t), \dot{\mathbf{w}}, t) \right) dt$$

- Invoke Fundamental Theorem of Calculus of Variation: $\delta J_a(\mathbf{w}^*(t), \mathbf{p}^*(t), \delta \mathbf{x}, \delta \mathbf{p}, t) = 0$
- The variations $\delta \mathbf{x}$ and $\delta \mathbf{p}$ are independent from one another.

The first order necessary conditions are

$$\text{Euler equation : } \begin{cases} \frac{\partial g_a(\mathbf{w}(t), \mathbf{p}(t), \dot{\mathbf{w}}, t)}{\partial \mathbf{w}} - \frac{d}{dt} \left[\frac{\partial g_a(\mathbf{w}(t), \mathbf{p}(t), \dot{\mathbf{w}}, t)}{\partial \dot{\mathbf{w}}} \right] = 0, \\ \frac{\partial g_a(\mathbf{w}(t), \mathbf{p}(t), \dot{\mathbf{w}}, t)}{\partial \mathbf{p}} - \frac{d}{dt} \left[\frac{\partial g_a(\mathbf{w}(t), \mathbf{p}(t), \dot{\mathbf{w}}, t)}{\partial \dot{\mathbf{p}}} \right] = 0, \end{cases}$$

$$\begin{cases} \frac{\partial g_a(\mathbf{w}(t), \mathbf{p}(t), \dot{\mathbf{w}}, t)}{\partial \mathbf{w}} - \frac{d}{dt} \left[\frac{\partial g_a(\mathbf{w}(t), \mathbf{p}(t), \dot{\mathbf{w}}, t)}{\partial \dot{\mathbf{w}}} \right] = 0, & (\mathbf{n} + \mathbf{m} \text{ dimensional}) \\ \mathbf{w}(t_0) = \mathbf{w}_0, \\ \mathbf{w}(t_f) = \mathbf{w}_f, \end{cases}$$
$$\mathbf{f}(\mathbf{w}, \dot{\mathbf{w}}, t) = 0, \quad (\mathbf{n} \text{ dimensional}).$$

- $\mathbf{w}^*(t) : \mathbb{R} \rightarrow \mathbb{R}^{\mathbf{n} + \mathbf{m}}, \mathbf{p}^*(t) : \mathbb{R} \rightarrow \mathbb{R}^{\mathbf{n}}$
